Earth seismic synchronous pendulum

Boyko Georgiev Iliev,Bankya,Bulgaria,64,"St.Stambolov",str., emaul: eqpboyko@abv.bg

Abstract. In science, there are some cases, where we cannot intervene making any analysis in order to monitor certain cause-and-effect relationship. Then we have to apply the approach of accumulation of already ascertained coincidences or observed phenomena, which could be somehow related to the problem, subject to our study. For instance, if the statement is that the earth axis makes 24-hour periodic vibrations (Figure 1) and that these vibrations are the cause of earthquakes, then we shall have to search for coincidences, relationships between earthquakes and the vibrations of the earth axis. We cannot stop the vibrations of the earth axis and see if earthquakes shall stop. Other visible phenomena due to the shake of the earth axis could be as follows: spiral movement of submarine streams in oceans, spiral movement of tectonic plates, the so called "Corkscrew theory", friction between tectonic plates. Two new relations between the tidal force of the Moon and earthquakes have been found in the researches bellow. A conclusion about a new theory of earthquake mechanism is derived from these relations.

Key words Earth,pendulum,axis,earthquakes.

Fig. 1

The theory

Earth can be considered as a giant mathematical pendulum with length, equal to the mean earth radius, R = 6372 795.5 m. The period of any mathematical pendulum is determined by the following formula:

$$T = 2.\pi \sqrt{\frac{R}{g}} \qquad (1)$$

Methods and data

The basic method of operating with the data is to find the average value of the time interval between two earthquakes. The average value is interesting because it is constant. This value shall be compared to the data obtained from the theory described above. In the first case, the mean value of the interval of time between two earthquakes has been calculated, without any preset conditions. It turns out that it is equal to 12.01 hours, or 12 h 06 min, Table 3 and Diagram 3. This case shall be commented in the conclusions. In the second case the mean interval of time between two earthquakes has been found, but under the condition that the earthquakes have happened in an interval from 0 to 4 hours. It is shown in Tables 1 and 2. The respective diagram is attached to each of the tables. In the interval from 0 to 4 hours, there is coincidence between the data from the theory and measuring. This coincidence shall be commented in the conclusions part. The data regarding the earthquakes on Earth have been taken from a catalogue of earthquakes published in internet. In this case, the data were taken from USGS American Catalogue of Earthquakes at http://earthquake.gov/earthquakes. In this case, the data concerning the earthquakes were selected from 1 January 1973 through 20 November 2011. In Table 1 and Table 2 bellow, at the respective randomly selected geographic coordinates, the total number of earthquakes found are shown, and how many of them have happened in an interval from 0 to 4 hours. With respect to those ones which happened within this interval, the average value between two earthquakes was calculated. In this case it is not important if two earthquakes happened in the same geographic place, or not. The interval from 0 to 4 hours between two earthquakes is relevant. The average interval is for them, which shall be compared with theoretical period of vibration of the earth axis calculated above.

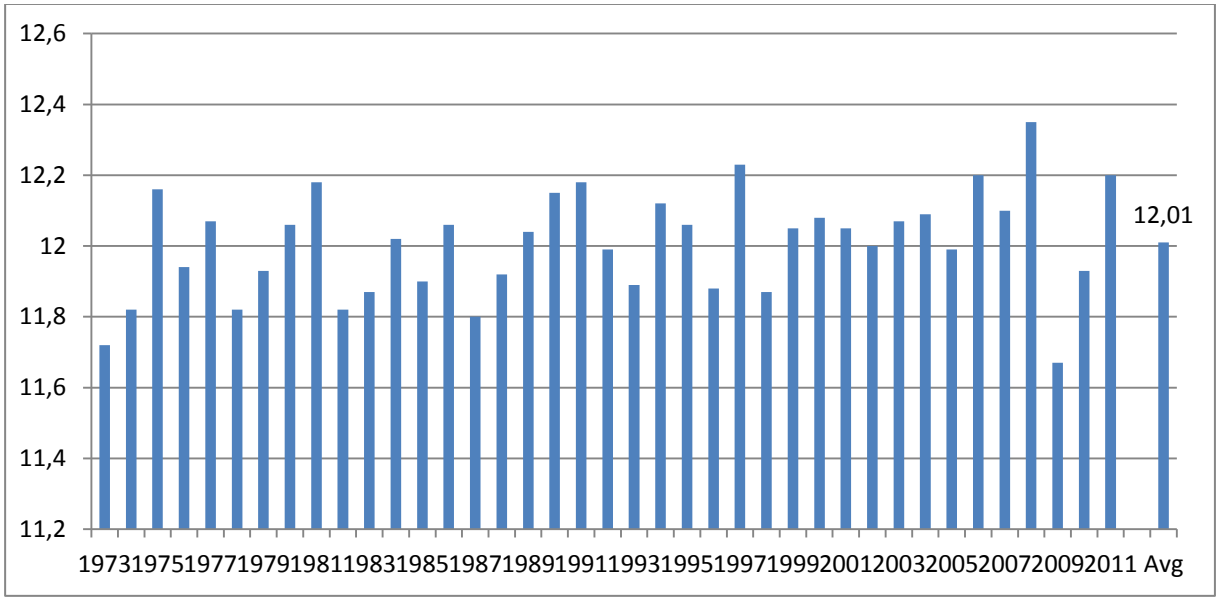
Mean interval between two earthquakes: 12 h 06 min



Conclusions

In the part of Methods and Data it was mentioned about a calculation made, of the mean value between two earthquakes under no conditions, Table 3. The mean interval between two earthquakes was 12.01 hours, ± 6 minutes of error. This measurement coincides with the fact that at one and the same physical moment, both tidal forces exerted on Earth and caused by the gravitation of the Moon are at a distance of 12 hours from each other. These 12 hours express the relationship between earthquakes and Moon tidal forces exerted on Earth. We can read about Moon tidal forces in „Курс общей астрономии" ('General Astronomy Course'), 1983, by Bakulin, Kononovich and Moroz, page 99. On page 101 of the same textbook, it is stated that the elevation of the earth crust caused by the Moon tidal force can achieve several decimeters. The mean interval between between two earthquakes happened within the interval from 0 to 4 hours from all the 20 measurements in Tables 1 and 2 is exactly 5078 seconds, or 1 hour, 24 minutes and 38 seconds. In the theory above, the period of vibration of the earth axis was calculated. It is equal to 1 hour, 24 minutes and 23 seconds. The difference of 15 seconds is insignificant. Such a coincidence can happen only and exclusively if the earth axis makes 24-hour periodical vibrations with the theoretical period mentioned above, falling into synchronization with earthquake epicenters. The shake of the Earth has been rhythmically conveyed to earthquakes too. But it means that not only tectonic plates are the trigger of earthquakes. Provided that synchronization is absolute, then a stronger earthquake shall happen, as the points over the epicenter shall be longer under the impact of the Moon. The friction between the layers decreases and if a seismic stress is accumulated, earthquake occurs. Layers begin to move. This can be seen in line number 7 in Table 2. In this case the theoretical period and the interval between two earthquakes almost coincide, i.e. the synchronization is absolute. This is revealed on Diagram 2. As an example we can refer to the earthquake of the town of Pernik on May 22nd, 2012. The main shock occurred at 03:00 a.m., and 1 hour and 30 minutes later, the second shock came, i.e. at 04:30 a.m., and its magnitude was 4.5. The difference in synchronization was 6 minutes only. Where is the effect of the Moon in this case? That very day, the Moon was at its superior culmination with respect to the latitude of Sofia. At that very moment, the tidal force of the Moon would make only one movement on earth crust, which should be synchronized with the shake of earth axis. Reference: 'Astronomical Calendar', 2012, published by the Bulgarian Academy of Sciences. Therefore, for full synchronization, the Moon has to be at its superior culmination and then we shall observe two intensive shocks at an interval of 1 hour, 24 minutes and 23 seconds averagely.
A new picture of earthquake mechanism theory appears:
Tectonic plates only prepare earthquakes, accumulating seismic stress, but the earthquake does not happen yet.
The Moon elevates the layers on both sides the Earth by the tidal forces between the tectonic plates and, at the right moment, falls into synchronization with the shake of the earth axis.
Swaying, the earth axis retains for a longer time the points submitted to Moon gravitation and then all the earthquakes happen.
The more intensive earthquakes occur in the presence of full synchronization and superior culmination of the Moon with respect to the corresponding geographical coordinates.
Any other earthquakes occur in the presence of partial synchronization. Reference: Diagram 2**.**
